What is truth?

One collaborator reported using the determination **True** to indicate that the issue reported by the alert was a real problem in the code.

Another collaborator used **True** to indicate that *something* was wrong with the diagnosed code, even if the specific issue reported by the alert was a **false positive**!

Solution: Lexicon And Rules

- We developed a **lexicon** and auditing **rule set** for our collaborators
- Includes a standard set of well-defined **determinations** for static analysis alerts
- Includes a set of **auditing rules** to help auditors make consistent decisions in commonly-encountered situations

Different auditors should make the **same determination** for a given alert!

Improve the **quality and consistency** of audit data for the purpose of building **machine learning classifiers**

Help organizations make **better-informed** decisions about **bug-fixes**, **development**, and **future audits**.

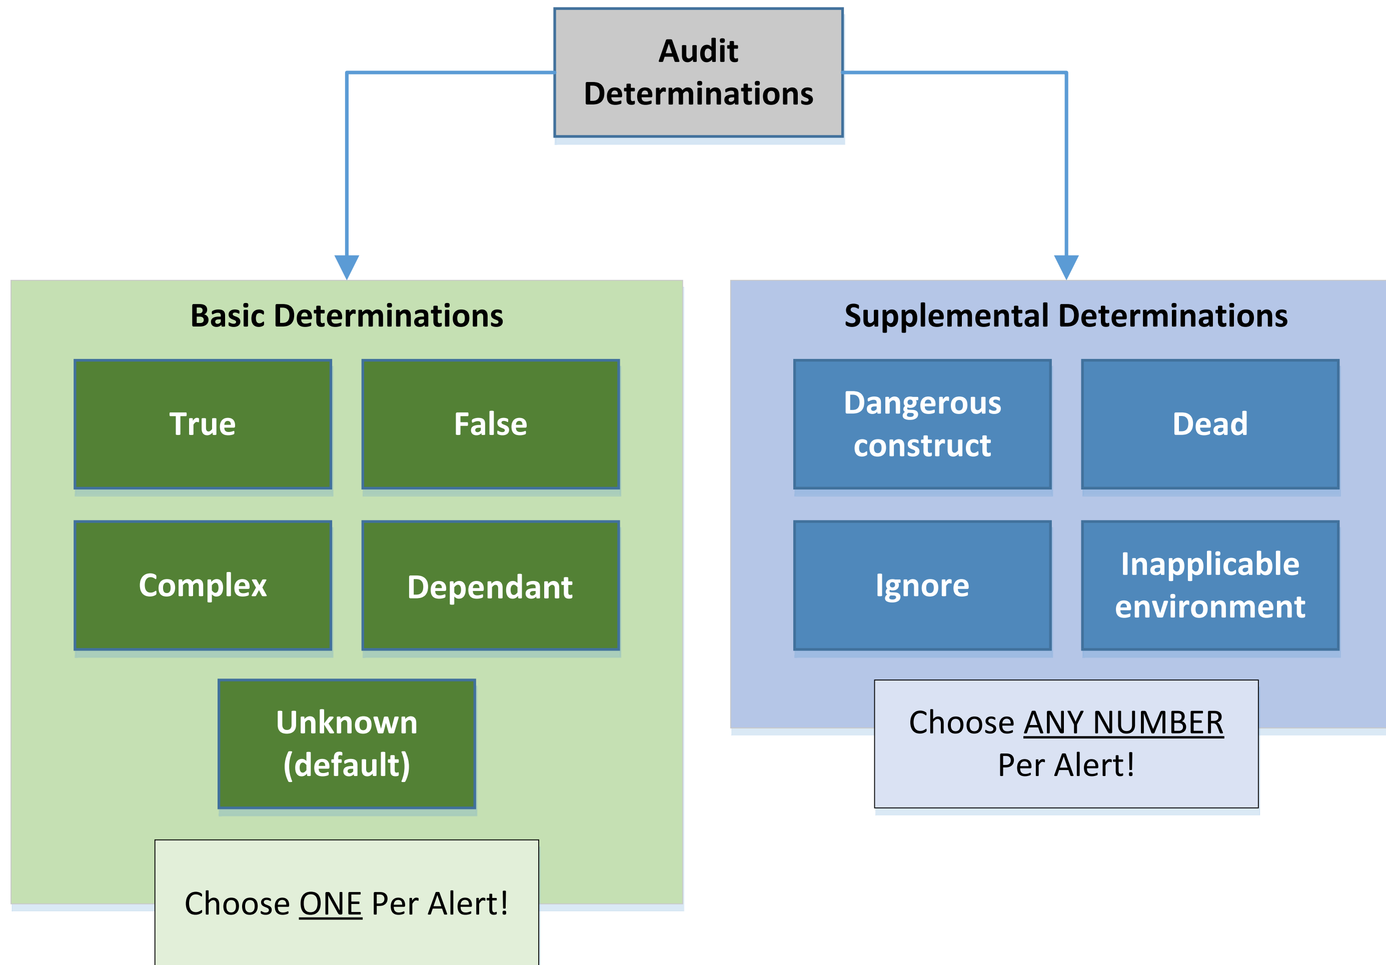
Audit Lexicon And Rules

Lexicon

© 2016 Carnegie Mellon University

[DISTRIBUTION STATEMENT A] This material has been approved for public release and unlimited distribution.

Lexicon: Audit Determinations



© 2016 Carnegie Mellon University
[DISTRIBUTION STATEMENT A] This material has been approved for public release and unlimited distribution.

Lexicon: Basic Determinations

True

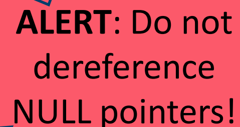
- The code in question violates the **condition** indicated by the alert.
  - E.g. A valid program should not deference NULL pointers.
- The condition can be determined from the definition of the alert itself, or from the **coding taxonomy** the alert corresponds to.
  - CERT Secure Coding Rules
  - CWEs

© 2016 Carnegie Mellon University
[DISTRIBUTION STATEMENT A] This material has been approved for public release and unlimited distribution.

Lexicon: Basic Determinations
True Example

```c
char *build_array(size_t size, char first) {
	if(size == 0) {
		return NULL;
	}

	char *array = malloc(size * sizeof(char));
	array[0] = first;
	return array;
}
```



Determination:
TRUE

© 2016 Carnegie Mellon University
[DISTRIBUTION STATEMENT A] This material has been approved for public release and unlimited distribution.

Lexicon: Basic Determinations

False

- The code in question does **not** violate the **condition** indicated by the alert.

```
char *build_array(int size, char first) {
        if(size == 0) {
                return NULL;
        }

        char *array = malloc(size * sizeof(char));
        if(array == NULL) {
                abort();
        }
        array[0] = first;
        return array;
}
```

Determination: **FALSE**

ALERT: Do not dereference NULL pointers!

© 2016 Carnegie Mellon University
[DISTRIBUTION STATEMENT A] This material has been approved for public release and unlimited distribution.

Lexicon: Basic Determinations

Complex

- The alert is **too difficult** to judge in a **reasonable amount of time and effort**
- “Reasonable” is defined by the individual organization.

Dependent

- The alert is related to a **True** alert that occurs earlier in the code.
- Intuition: fixing the first alert would implicitly fix the second one.

Unknown

- None of the above. This is the default determination.

© 2016 Carnegie Mellon University
[DISTRIBUTION STATEMENT A] This material has been approved for public release and unlimited distribution.

Lexicon: Basic Determinations Dependent Example

```
char *build_array(size_t size, char first, char last) {
      if(size == 0) {
            return NULL;
      }

      char *array = malloc(size * sizeof(char));
      array[0] = first;
      array[size - 1] = last;
      return array;
}
```

ALERT: Do not dereference NULL pointers!

Determination: **TRUE**

ALERT: Do not dereference NULL pointers!

Determination: **DEPENDENT**

© 2016 Carnegie Mellon University
[DISTRIBUTION STATEMENT A] This material has been approved for public release and unlimited distribution.

Lexicon: Supplemental Determinations

Dangerous Construct

- The alert refers to a piece of code that poses **risk** if it is not modified.
- Risk level is specified as **High**, **Medium**, or **Low**
- Independent of whether the alert is true or false!

Dead

- The code in question **not reachable at runtime.**

Inapplicable Environment

- The alert does not apply to the current environments where the software runs (OS, CPU, etc.)
- If a new environment were added in the future, the alert may apply.

Ignore

- The code in question does not require mitigation.

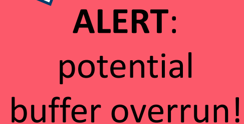
[DISTRIBUTION STATEMENT A] This material has been approved for public release and unlimited distribution.

Lexicon: Supplemental Determinations Dangerous Construct Example

```
#define BUF_MAX 128

void create_file(const char *base_name) {
      // Add the .txt extension!
      char filename[BUF_MAX];
      snprintf(filename, 128, "%s.txt", base_name);

      // Create the file, etc...
}
```



Seems ok…but why not use **BUF_MAX** instead of 128?

Determination:
False
+
Dangerous Construct

Audit Lexicon And Rules

Rules

© 2016 Carnegie Mellon University
[DISTRIBUTION STATEMENT A] This material has been approved for public release and unlimited distribution.

Auditing Rules

Goals

- Clarify **ambiguous or complex** auditing scenarios
- Establish **assumptions** auditors can make
- Overall: help make audit determinations **more consistent**

We developed **12 rules**

- Drew on our own experiences auditing code bases at CERT
- Trained 3 groups of engineers on the rules, and incorporated their feedback
- In the following slides, we will inspect three of the rules in more detail.

© 2016 Carnegie Mellon University
[DISTRIBUTION STATEMENT A] This material has been approved for public release and unlimited distribution.

Example Rule: Assume external inputs to the program are malicious

An auditor should assume that **inputs to a program module** (e.g. function parameters, command line arguments, etc.) may have arbitrary, **potentially malicious**, values.

- Unless they have a strong guarantee to the contrary

Example from recent history: **Java Deserialization**

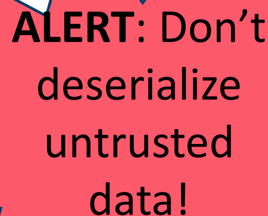
- An auditor can assume that external data passed to the `readObject` deserialization routine may be malicious
  - Assuming there are no other mitigations in place
  - See: **SER12-J, Prevent deserialization of untrusted data**

© 2016 Carnegie Mellon University
[DISTRIBUTION STATEMENT A] This material has been approved for public release and unlimited distribution.

Audit Rules
External Inputs Example

```java
import java.io.*;

class DeserializeExample {
    public static Object deserialize(byte[] buffer)
            throws Exception {
        ByteArrayInputStream bais;
        ObjectInputStream ois;
        bais = new ByteArrayInputStream(buffer);
        ois = new ObjectInputStream(bais);
        return ois.readObject();
    }
}
```



Without strong evidence to the contrary, assume the buffer could be malicious!

Determination: **TRUE**

© 2016 Carnegie Mellon University
[DISTRIBUTION STATEMENT A] This material has been approved for public release and unlimited distribution.

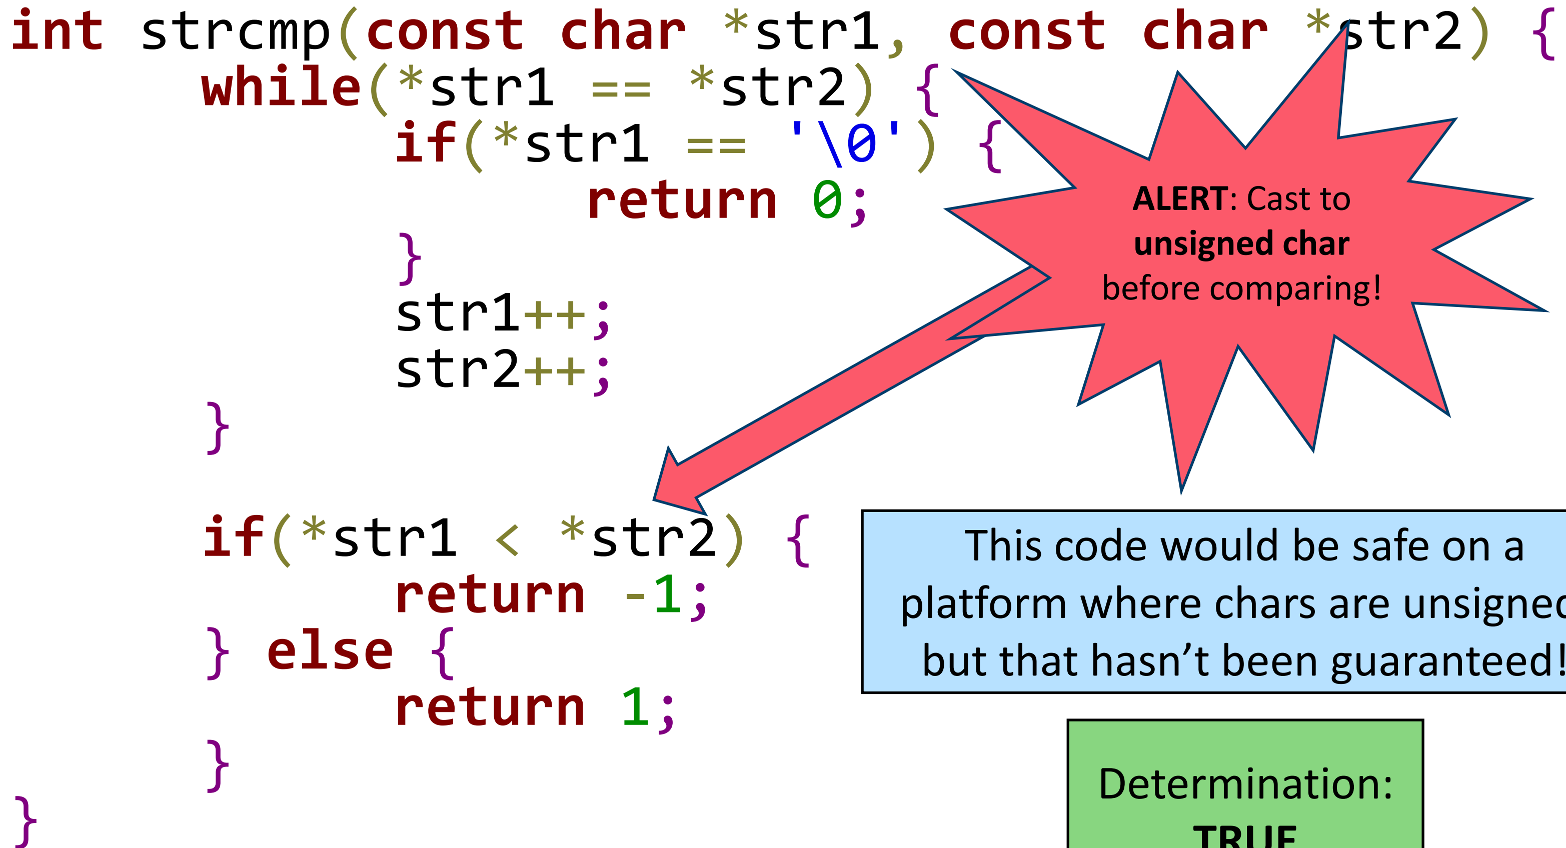
Example Rule: Unless instructed otherwise, assume code must be portable.

When auditing alerts for a code base where the target platform is **not specified**, the auditor should **err on the side of portability**.

If a diagnosed segment of code **malfunctions on certain platforms**, and in doing so violates a condition, this is suitable justification for marking the alert **True**.

© 2016 Carnegie Mellon University
[DISTRIBUTION STATEMENT A] This material has been approved for public release and unlimited distribution.

Audit Rules
Portability Example



© 2016 Carnegie Mellon University
[DISTRIBUTION STATEMENT A] This material has been approved for public release and unlimited distribution.

Example Rule: Handle an alert in unreachable code depending on whether it is exportable.

Certain code segments may be **unreachable** at runtime. Also called **dead code.**

A static analysis tool might not be able to realize this, and **still mark alerts** in code that **cannot be executed**.

The **Dead** supplementary determination can be applied to these alerts. However, an auditor should **take care** when deciding if a piece of code is truly dead.

In particular: just because a given program module (function, class) is not used does **not** mean it is dead. The module might be exported as a **public interface**, for use by another application.

This rule was developed as a result of a scenario encountered by one of our collaborators!

© 2016 Carnegie Mellon University
[DISTRIBUTION STATEMENT A] This material has been approved for public release and unlimited distribution.

Future Work

- Gather feedback on our lexicon and rules from surveys, focus groups, experts, etc.
- Continue to refine the lexicon/rules.
- Further develop CERT's SCALe auditing framework to fully incorporate these concepts.
- Work with more collaborators to test the rules/lexicon in practice.
  - We have some initial feedback from two collaborators, who used our rules to audit several hundred alerts from C and Java codebases
